Forms in Angular

A lot of applications are very form-intensive, especially for enterprise development.

Forms can end up being really complex:

- Form inputs are meant to **modify data**, both on the page and the server
- Users cannot be trusted in what they enter, so you need to **validate** values
- The UI needs to clearly **state expectations** and errors
- **Dependent fields** can have complex logic
- We want to be able to **test** our forms, without relying on DOM selectors

Form states such as being: **valid, invalid, pristine, dirty, untouched, touched, disabled, enabled, pending..etc**

Two Modules

Angular has the `@angular/forms` package with two modules:

FormsModule (Template Driven Forms)

We create a form by placing directives in the template. We then use data bindings to pass the data from and to that form.

ReactiveFormsModule (Data Driven Forms)

We define a form in the component class and bind it to elements in the template. Because we use reactive programming to pass data in and out of the form, we call it “reactive”.

Importing Form Modules

```
import { FormsModule, ReactiveFormsModule } from '@angular/forms';
@NgModule({
  declarations: [ ],
  imports: [ BrowserModule,
    FormsModule,
    ReactiveFormsModule ]
})
```

By importing `FormsModule` or `ReactiveFormsModule` into our `NgModule` means we can use all directives exported from these modules in our view template.

High-Level Form Programming

Form Model

The form model is a UI-independent representation of a form. There are three building blocks: **FormControl**, **FormGroup**, and **FormArray**. All of these are available in both **FormsModule** and **ReactiveFormsModule**.

Form Directives

These directives connect the form model to the DOM. **FormsModule** and **ReactiveFormsModule** provide different sets of these directives.

DOM

These are DOM inputs, checkboxes, and radio buttons.

10. NgForm Directive

11. NgModel Directive

Angular Form Models

- **FormControl** an indivisible part of the form, an atom. It usually corresponds to a simple UI element, such as an input. It has a **value**, **status**, and a map of **errors**
- **FormGroup** A fixed-size collection of controls. The value of a group is just an aggregation of the values of its children.
- **FormArray** A collection of the same control type as FormGroup of a variable length.
- **Validator** give us the ability to validate inputs.
- **Observers** let us watch our form for changes and respond accordingly.

Why Form Model?

The form model is a UI-independent way to represent user input consist of simple controls (`FormControl`) and their combinations (`FormGroup` and `FormArray`), where each control has a value, status, validators, errors, it emits events and it can be disabled.

Having this model has the following advantages:

- Form handling is a complex problem. Splitting it into UI-independent and UI-dependent parts makes them easier to manage. And we can test form handling without rendering UI.
- Having the form model makes reactive forms possible.

9. Form Directives

10. NgForm Directive

11. NgModel Directive

NgForm Directive

NgForm directive's selector is the `<form>` tag. It will get automatically attached to any `<form>` tags and makes `ngForm` available to our view.

How does it work?

By adding the `<form>` tag in a template, the directive will trigger and creates a new `FormGroup` instance named `ngForm` and it will give us an `(ngSubmit)` output

10

6. High-Level Form Programming

7. Angular Form Models

8. Why Form Model?

9. Form Directives

10. NgForm Directive

11. NgModel Directive

NgModel Directive

NgModel directive has a selector of **ngModel**, This means we can attach it to any form element as an attribute:

ngModel="var" (var is property in our component class).

How does it work?

By adding **ngModel** to UI elements, Angular creates a new **FormControl** that is automatically added to the parent **FormGroup** and then binds the new **FormControl** to the DOM element.

9. Form Directives

10. NgForm Directive

11. NgModel Directive

Template Driven Form

```

<form #f="ngForm" (ngSubmit)="onSubmit(f)">
  <input type="text"
    name="email"
    ngModel
    required
    pattern="[a-zA-Z0-9]+@[a-zA-Z0-9]+\.[a-zA-Z0-9]{2,4}"
    #email="ngModel">
  <div *ngIf="!email.valid"> Invalid email </div>
  <button type="submit" [disabled]="!f.valid">Submit</button>
</form>
<!-- Component Body -->
@Component({...})
export class TemplateDrivenComponent {
  onSubmit(form) {
    console.log(form.value);
  }
}

```

Easy trick for an alias to **ngForm** , to enable/disable the submit button

Easy trick to access ngModel in the view so we can display error messages

form.value will return the key/value pairs of this FormGroup

12

2. Maharishi University of Management - Fairfield, Iowa
3. Forms in Angular
4. Two Modules
5. Importing Form Modules

7. Angular Form Models
8. Why Form Model?
9. Form Directives
10. NgForm Directive
11. NgModel Directive
12. Template Driven Form

Two-way Data-binding (REVISIT)

```

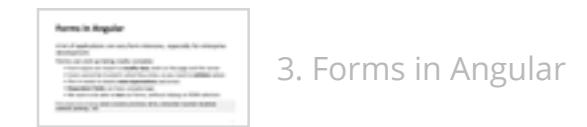

@Component({
  selector: 'comp',
  template: `
    <p>Message: {{message}}</p>
    <input [value]="message" (input)="message=$event.target.value">
    <input [(ngModel)]="message" />`
})
export class CompComponent {
  public message: string = 'Default Message';
}

```

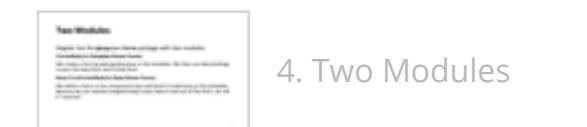

ngModel binds a model to a form. ngModel can implement two-way data binding. Remember that two-way data binding is more complicated and difficult to reason about! Use it sparingly.

Bind the input element to **ngModel**:
 [] as input to take the value from the Component
 () as output to save the value in the Component

Using FormBuilder

FormBuilder is a service that helps us build forms and give us a lot of customization options.

Forms are made up of **FormControl** and **FormGroup** and the **FormBuilder** helps us create them (you can think of it as a factory object).

16

14. Data Driven Forms

15. Using FormBuilder

Data Driven Forms Directives

We want to link our `<form>` UI to the `myForm` object that we created in our Component.

When we want to bind an existing **FormGroup** to a **form** we use the directive **formGroup**

When we want to bind an existing **FormControl** to an **input** we use the directive **formControl**

17

6. High-Level Form Programming

7. Angular Form Models

14. Data Driven Forms

15. Using FormBuilder

16. Data Driven Forms Directives

Reactive Forms with FormBuilder

To start building a Data-Driven Form we inject **FormBuilder** service in the constructor of our component class.

During injection an instance of **FormBuilder** will be created.

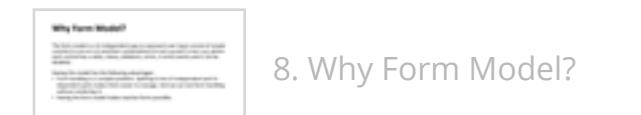

```
@Component({...})
export class DataDrivenComponent {
  myForm: FormGroup;
  constructor(private fb: FormBuilder) {
    this.myForm = fb.group({
      'email': ['asaad@mum.edu']
    });
  }
  onSubmit(): void {
    console.log('you submitted value: ', this.myForm.value);
  }
}
```

There are two main methods on FormBuilder:
control() - creates a new **FormControl**
group() - creates a new **FormGroup**

16. Data Driven Forms Directives

17. Reactive Forms with FormBuilder

Using myForm in the view

```

<form [formGroup]="myForm" (ngSubmit)="onSubmit()">
  <input type="text"
    name="email"
    [formControl]="myForm.get('email')">
  <div *ngIf="!myForm.get('email').valid">Invalid email</div>
  <div *ngIf="myForm.get('email').hasError('invalid')">Error</div>
  <button type="submit" [disabled]="!myForm.valid">Submit</button>
</form>

```

Inspect the code and see how angular adds all kind of state change classes to the form elements.

formControlName="email"

Main Points

Template Driven Forms

To create a new **FormGroup** and **FormControl** implicitly we use the following directives in our template:

- **ngForm**
- **ngModel**

Data Driven Forms

To bind to an existing **FormGroup** and **FormControl** from your component to your template we use the following directives:

- **formGroup**
- **formControl**

20

9. Form Directives

14. Data Driven Forms

15. Using FormBuilder

16. Data Driven Forms Directives

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

Add Validation

Validators change the status of **FormControl**/**FormGroup**.
 To assign a validator to a **FormControl** object we simply pass it as the **second argument** to our **FormControl** constructor:

```
@Component({...})
export class DataDrivenComponent {
  myForm: FormGroup;
  constructor(fb: FormBuilder) {
    this.myForm = fb.group({
      'email': ['asaad@mum.edu', Validators.required]
    })
  }
}
```

To use more than one validator:

```
'email': ['asaad@mum.edu', Validators.compose([Validators.required, Validators.email]) ]
```

The compose function will execute all the validators and merge the errors.

14. Data Driven Forms

15. Using FormBuilder

16. Data Driven Forms Directives

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

20. Add Validation

Custom Validators

A validator is a function that takes a **FormControl** as an input and returns a **StringMap<string, boolean>** where the key is error code and the value is true if it fails

```
exampleValidator(control: FormControl): {[s: string]: boolean} {
  if (control.value === 'Example') {
    return {'invalid': true};
  }
  return null;
}
```

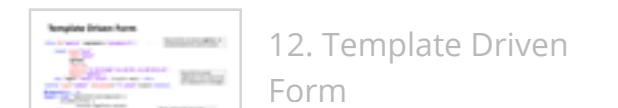

Returning null means validation is valid.

Returning anything else means validation is invalid.

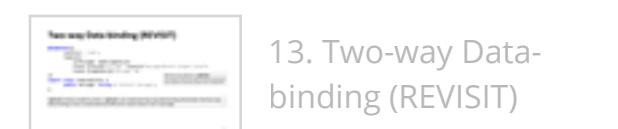

22

15. Using FormBuilder

16. Data Driven Forms Directives

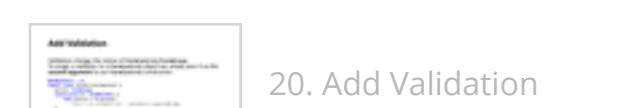

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

20. Add Validation

21. Custom Validators

Custom Asynchronous Validators

Asynchronous validator is a function that takes a **FormControl** as its input and returns a **Promise<any>** or an **Observable<any>**

```
asyncValidator(control: FormControl): Promise<any> | Observable<any> {
  const promise = new Promise<any>((resolve, reject) => {
    setTimeout(() => { if (control.value === 'Example') {
      resolve({ 'invalid': true });
    } else {
      resolve(null);
    }
  }, 1500);
  return promise;
}
```

While the promise or the observable being resolved, the status of the form will be PENDING

23

17. Reactive Forms with FormBuilder

18. Using myForm in the view

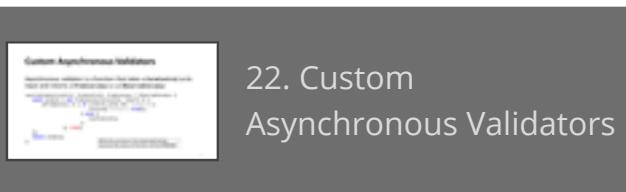

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

Watching For Changes

Both **FormGroup** and **FormControl** have an **EventEmitter** that we can use to observe changes.

Any time a control updates, it will emit the value.

To watch for changes on form/control we get access to the **EventEmitter/Observable** by calling **valueChanges** or **statusChanges** (valid, invalid, pending).

Since **valueChanges** and **statusChanges** are RxJS observables, we can use the rich set of RxJS operators to implement powerful user interactions in a just a few lines of code.

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

Main Point

Angular forms can be created via two ways: by using the **template-driven** approach or the **data-driven** approach.

- In the first approach (**template-driven**), Angular will automatically create a form with which it works by identifying the `<form>` tag. You will have to assign controls to this form by adding the `ngModel` directive to the HTML elements which should be form inputs/controls.
- In the **data-driven** approach, you create the form on your own (in the component body) and then assign it to the HTML code by using `FormGroup` for the form and `FormControl` for the individual controls.

15. Using FormBuilder

16. Data Driven Forms Directives

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

Authentication vs Authorization

Authentication is the process of identifying that somebody really is who they claim to be.

Authorization is the process of verifying that you have access to something.

The two concepts are completely independent, but both are central to security design, and the failure to get either one correct opens up the avenue to compromise.

Authentication = login + password (who you are)

Authorization = permissions (what you are allowed to do)

28

16. Data Driven Forms Directives

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

OAuth2 - Delegated Authorization

OAuth2 is a standard protocol that solves the delegated authorization problem.

Example: Users may give permission to "Photo Printing App" to access one album on "Google Photos" so the app can print it out or create a collage poster. This is a better way than giving the App our Google username/password to access Google Photos on our behalf.

Unfortunately some apps (Banks, Mint: financial dashboard) are still collecting username/password to access users data.

I trust Google but I kind of trust this new App. I want the App to have access to my contacts only.

17. Reactive Forms with FormBuilder

18. Using myForm in the view

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

Creating an App and receiving Client ID and Secret

Application must register with the Auth service (application name, website, a logo, etc.). We must also register a **redirect URI** to be used for redirecting users back to the application.

After registering the app, we will receive a **client ID** and a **client secret**. The client ID is considered public information, and is used to initiate the process of the login URL (can be included in JavaScript source code on a page). The client secret must be kept confidential.

Because SPA apps or native apps cannot keep the secret confidential, then the secret is not used.

18. Using myForm in the view

19. Main Points

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

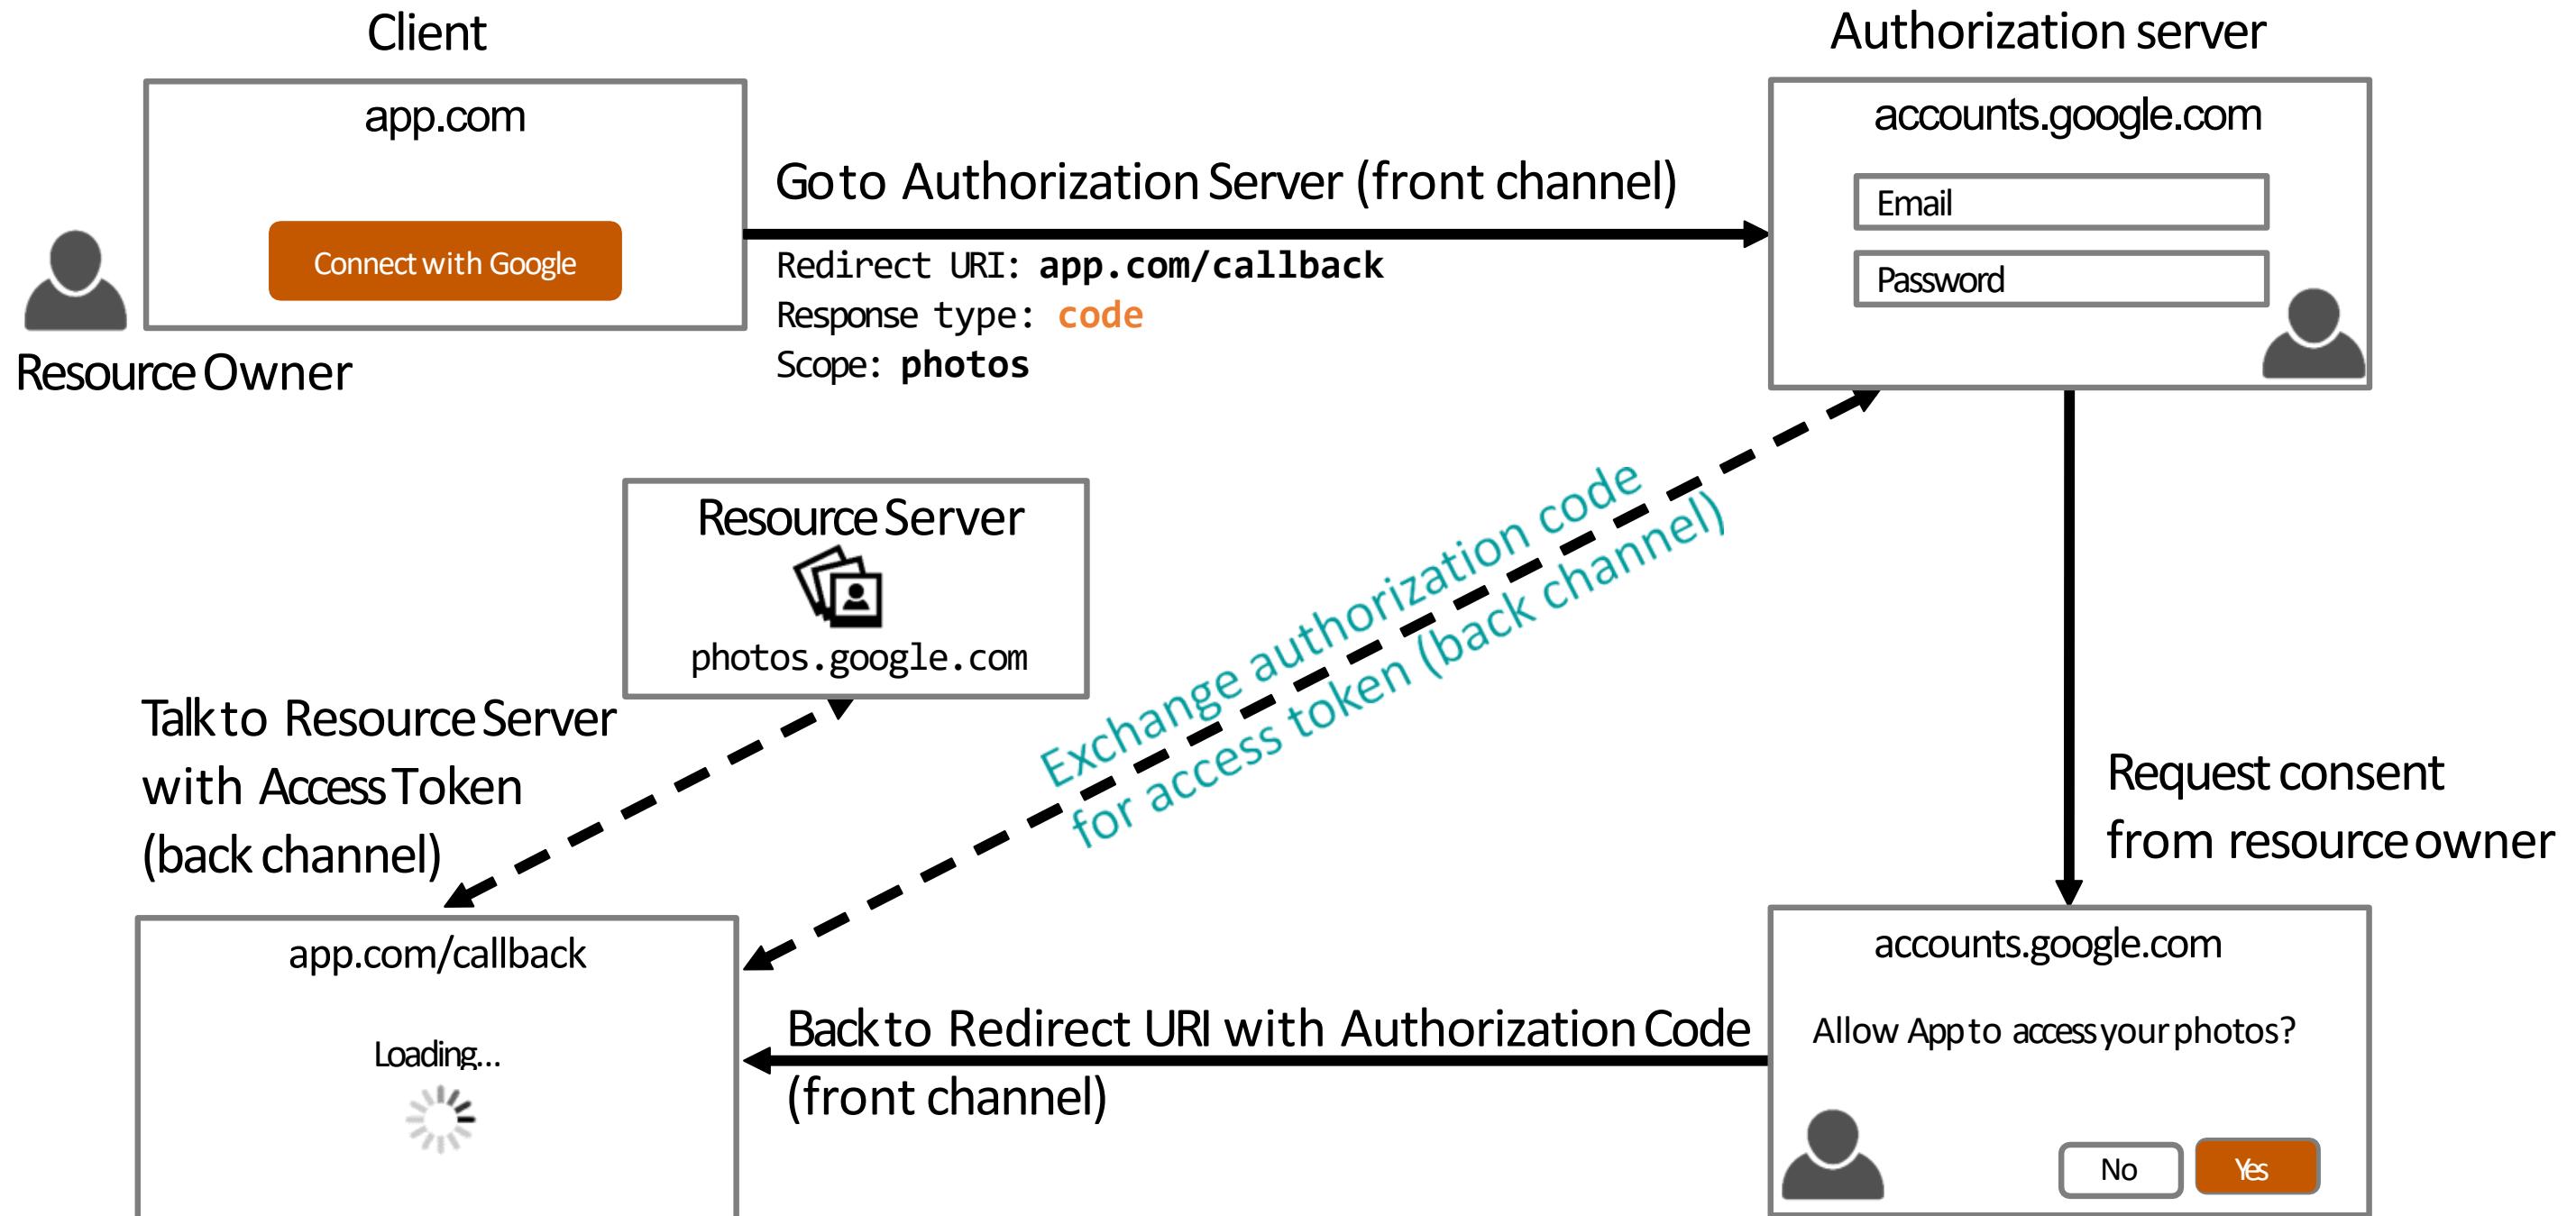

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

OAuth 2.0 Authorization Code Flow

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

29. OAuth 2.0 Authorization Code Flow

30. Starting the flow

Starting the flow

```
https://accounts.google.com/oauth2/?  
client_id=asaad123&  
redirect_uri=https://app.com/callback&  
scope=photos&  
response_type=code&  
state=foobar
```

The user sees the authorization prompt: because we are sending a **client_id**, the auth server will display a message: The **APP_NAME** by **AUTHOR** would like the ability to access your photos, allow or deny? If the user clicks "Allow," the service redirects the user back to your site with an auth code

20. Add Validation

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

29. OAuth 2.0 Authorization Code Flow

30. Starting the flow

Calling back

The server returns the authorization code in the query string along with the same state value that is passed

```
https://app.com/callback?
  error=access_denied&
  error_description=The user did not consent.
```

```
https://app.com/callback?
  code=oMsCeLvIaQm6bTrgtp7&
  state=foobar
```

You should first compare this state value to ensure it matches the one you started with. This ensures your redirection endpoint isn't able to be tricked into attempting to exchange arbitrary authorization codes.

21. Custom Validators

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

29. OAuth 2.0 Authorization Code Flow

30. Starting the flow

31. Calling back

Exchange code for an Access token

POST accounts.google.com/oauth2/token

Content-Type: application/x-www-form-urlencoded

```
code=oMsCeLvIaQm6bTrgtp7&
client_id=asaad123&
client_secret=secret123&
grant_type=authorization_code&
redirect_uri=https://app.com/callback&
```

Authorization server returns an Access token and expiration time

```
{
  "access_token": "fFAGRNJru1FTz70BzhT3Zg",
  "expires_in": 3920,
  "token_type": "Bearer",
}
```

22. Custom Asynchronous Validators

23. Watching For Changes

24. Example

25. Main Point

26. Authentication vs Authorization

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

29. OAuth 2.0 Authorization Code Flow

30. Starting the flow

31. Calling back

32. Exchange code for an Access token

Use the Access token

GET photos.google.com/api
Authorization: Bearer ffAGRNJru1FTz70BzhT3Zg

Resource Server will validate the token and use its scope for authorization

35. OAuth 2.0 Implicit Flow

36. OAuth 2.0 Authorization flow with PKCE

OAuth 2.0 Authorization flow with PKCE

Clients create a **Code Verifier** which is a random string that the app stores locally.

Send the code challenge along with your first request:

code_challenge=XXXXXXXX (base64-encoded version of the sha256 hash of the code verifier string)

code_challenge_method=S256 (hashing method used to compute the challenge)

When you exchange your authorization code with an access token, you need to include:

code_verifier=CODE_VERIFIER_STRING

The authorization server will hash the provided plaintext (same client ID) and confirm that the hashed version corresponds with the hashed string that was sent in the initial authorization request. This ensures the security of using the authorization code flow with clients that don't support a secret.

27. OAuth2 - Delegated Authorization

28. Creating an App and receiving Client ID and Secret

29. OAuth 2.0 Authorization Code Flow

30. Starting the flow

31. Calling back

34. OAuth 2.0 flows

35. OAuth 2.0 Implicit Flow

36. OAuth 2.0 Authorization flow with PKCE

37. ---

OAuth 2.0 is NOT for Authentication

People often misuse OAuth protocol for simple login or mobile apps login, which is bad, because there is no standard way to know the user's information, OAuth cares about permission and scope, whether your access token is scoped to access certain resource or not, it does not care of who you are.

- Companies added their own custom implementation differently
- No common set of scopes

28. Creating an App and receiving Client ID and Secret

JSON Web Token (JWT)

- 31. Calling back
- 32. Exchange code for an Access token
- 33. Use the Access token
- 34. OAuth 2.0 flows
- 35. OAuth 2.0 Implicit Flow
- 36. OAuth 2.0 Authorization flow with PKCE
- 37. ---
- 38. OAuth 2.0 is NOT for Authentication
- 39. OpenID Connect for Authentication
- 40. OpenID Connect authentication code flow
- 41. Exchange code for access token and ID token

What is JSON Web Token?

JSON Web Token (JWT) is an open standard that defines a compact and self-contained way for securely transmitting information between parties as a JSON object. This information can be verified and trusted because it is digitally signed.

Because of their smaller size, JWTs can be sent through a URL, POST parameter, or inside an HTTP header.

JWT is Self-contained: The payload contains all the required information about the user, avoiding the need to query the database more than once.

42. What is JSON Web Token?

43. What is the JSON Web Token structure?

JWT Structure

Header: Where we define the **algorithm** used to sign the token, as well as the token type.

Payload: This is where we keep a JSON object of all the **claims** we want. Claims can include those that are registered in the JWT spec, as well as any arbitrary data we want. Some of the reserved claims are: iss (issuer), exp (expiration time), sub (subject), aud (audience), and others.

Signature: The signature is where the signing action happens. To get the signature, we take the Base64URL encoded header, add the Base64URL encoded payload next to it, and run that string along with the secret key through the hashing algorithm we've chosen.

44. JWT Structure

The Bearer Schema

Whenever the user wants to access a protected route or resource, the user agent should send the JWT, typically in the Authorization header using the Bearer schema. The content of the header should look like the following:

Authorization: Bearer <token>

You may save the authorization data for the user in the JWT.

44. JWT Structure

45. The Bearer Schema

How Are JWTs Used to Authenticate Angular Apps?

- Users send their credentials to the server which are verified against a database. If everything checks out, a JWT is sent back to them.
- The JWT is saved in the user's browser by holding it in local storage.
- The presence of a JWT saved in the browser is used as an indicator that a user is currently logged in.
- The JWT's expiry time is continually checked to maintain an authenticated state in the app, and the user's details are read from the payload to populate views such as the their profile.
- Access to protected client-side routes (such as the profile area) are limited to only authenticated users via Guards
- When the user makes XHR requests to the API for protected resources, the request must be intercepted and the JWT gets sent as an Authorization header using the Bearer.
- Middleware on the server, which is configured with the app's secret key checks the incoming JWT for validity and, if valid, sends the response.

Passwordless Authentication

Passwordless authentication is a type of authentication where users do not need to login with passwords. Users may log in simply by a magic link, fingerprint, or using a token that is delivered securely via known email or text message.

60

Improve User Experience

The faster users can sign up and use your service, the more users your app tends to attract. Users do not like having to fill out forms and go through a long registration process.

Increase Security

Once you go passwordless, there are no passwords to be hacked.

48. Passwordless Authentication

49. OTPW One-Time Password

How Passwordless Authentication Works

- Instead of asking users for a password when they try to log in to your app or website, just ask them for their username (or email or mobile phone number).
- Create a temporary authorization code on the backend server and store it in your database.
- Send the user an email or SMS with a link that contains the code.
- The user clicks the link which opens your app or website and sends the authorization code to your server.
- On your backend server, verify that the code is valid and exchange it for a long-lived token, which is stored in your database and sent back to be stored on the client device as well. (There will also be checks on the server to ensure that the link was clicked within a certain period)
- The user is now logged in, and doesn't have to repeat this process again until their token expires or they want to authenticate on a new device.

Why Do We Need a Angular Compiler?

- The TS compiler will convert your TS code (types, decorators and classes) to ES 5/6 friendly code.
- But these function constructors will have templates written in Angular language and need to be converted to JS functionality to handle all the property bindings, change detection and the directives.. etc
- The Angular code **needs to be compiled** into functional JS logic (component factories when called it will generate the DOM elements)
- Finally after compilation the JS code is then sent to V8 to be: parsed into AST, from AST we generate bytecode, this code will be optimized and recompiled before being sent to the CPU.

48. Passwordless Authentication

49. OTPW One-Time Password

50. How Passwordless Authentication Works

51. Why Do We Need a Angular Compiler?

Just-in-time (JIT) compilation

It's known as **dynamic translation**, the compilation is done during execution of a program at runtime. When the user opens the browser, the following steps are performed:

- Download all the JavaScript assets (including the compiler code)
- Angular bootstraps
- Angular goes through the JIT compilation process generating all the JavaScript for each component in the application
- The application gets rendered.

48. Passwordless Authentication

49. OTPW One-Time Password

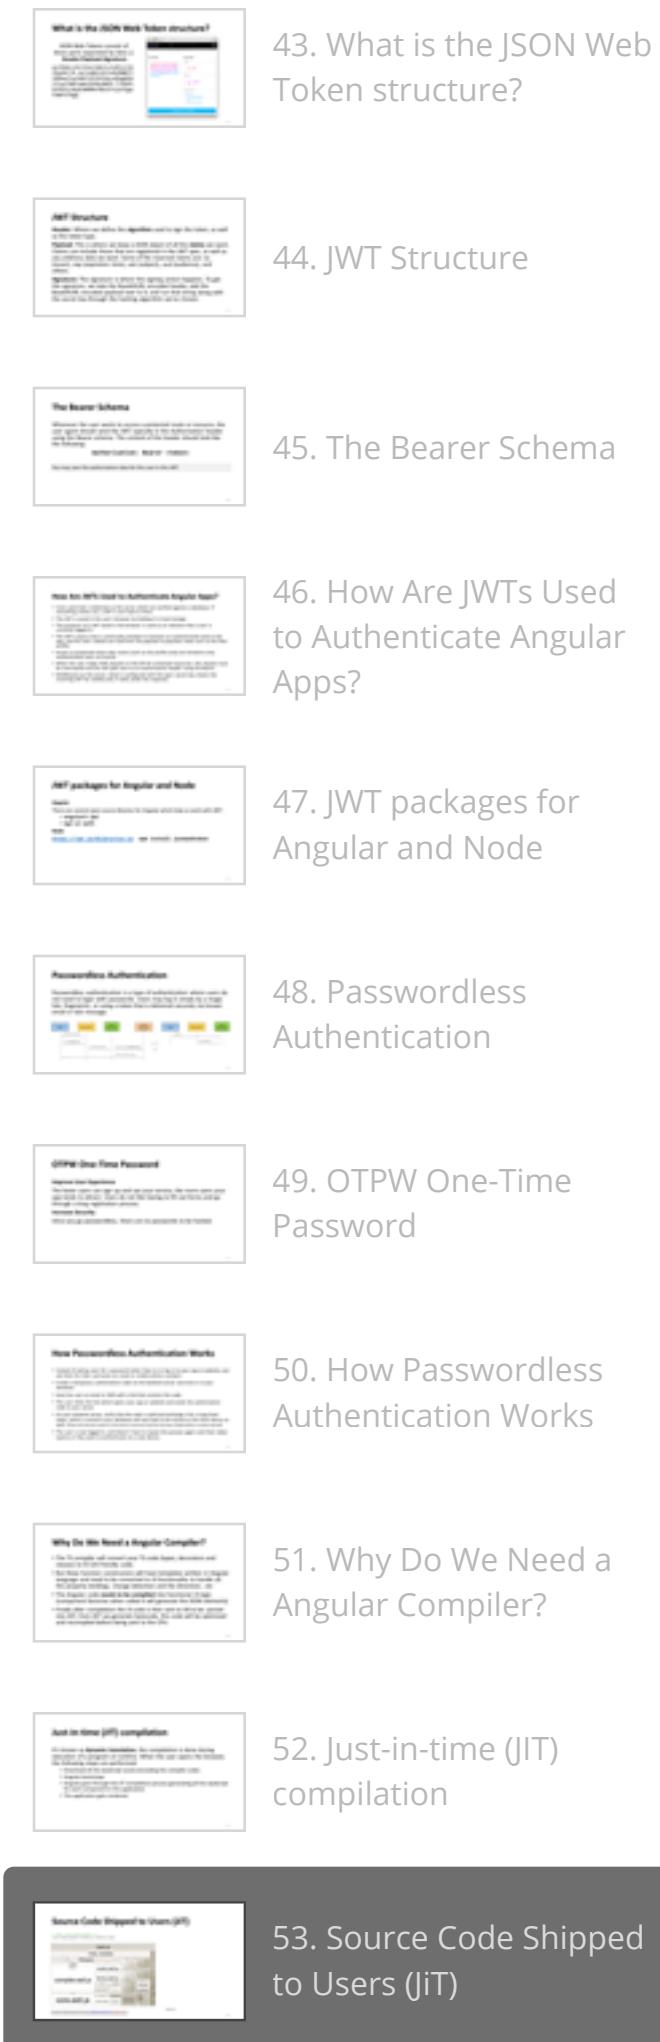

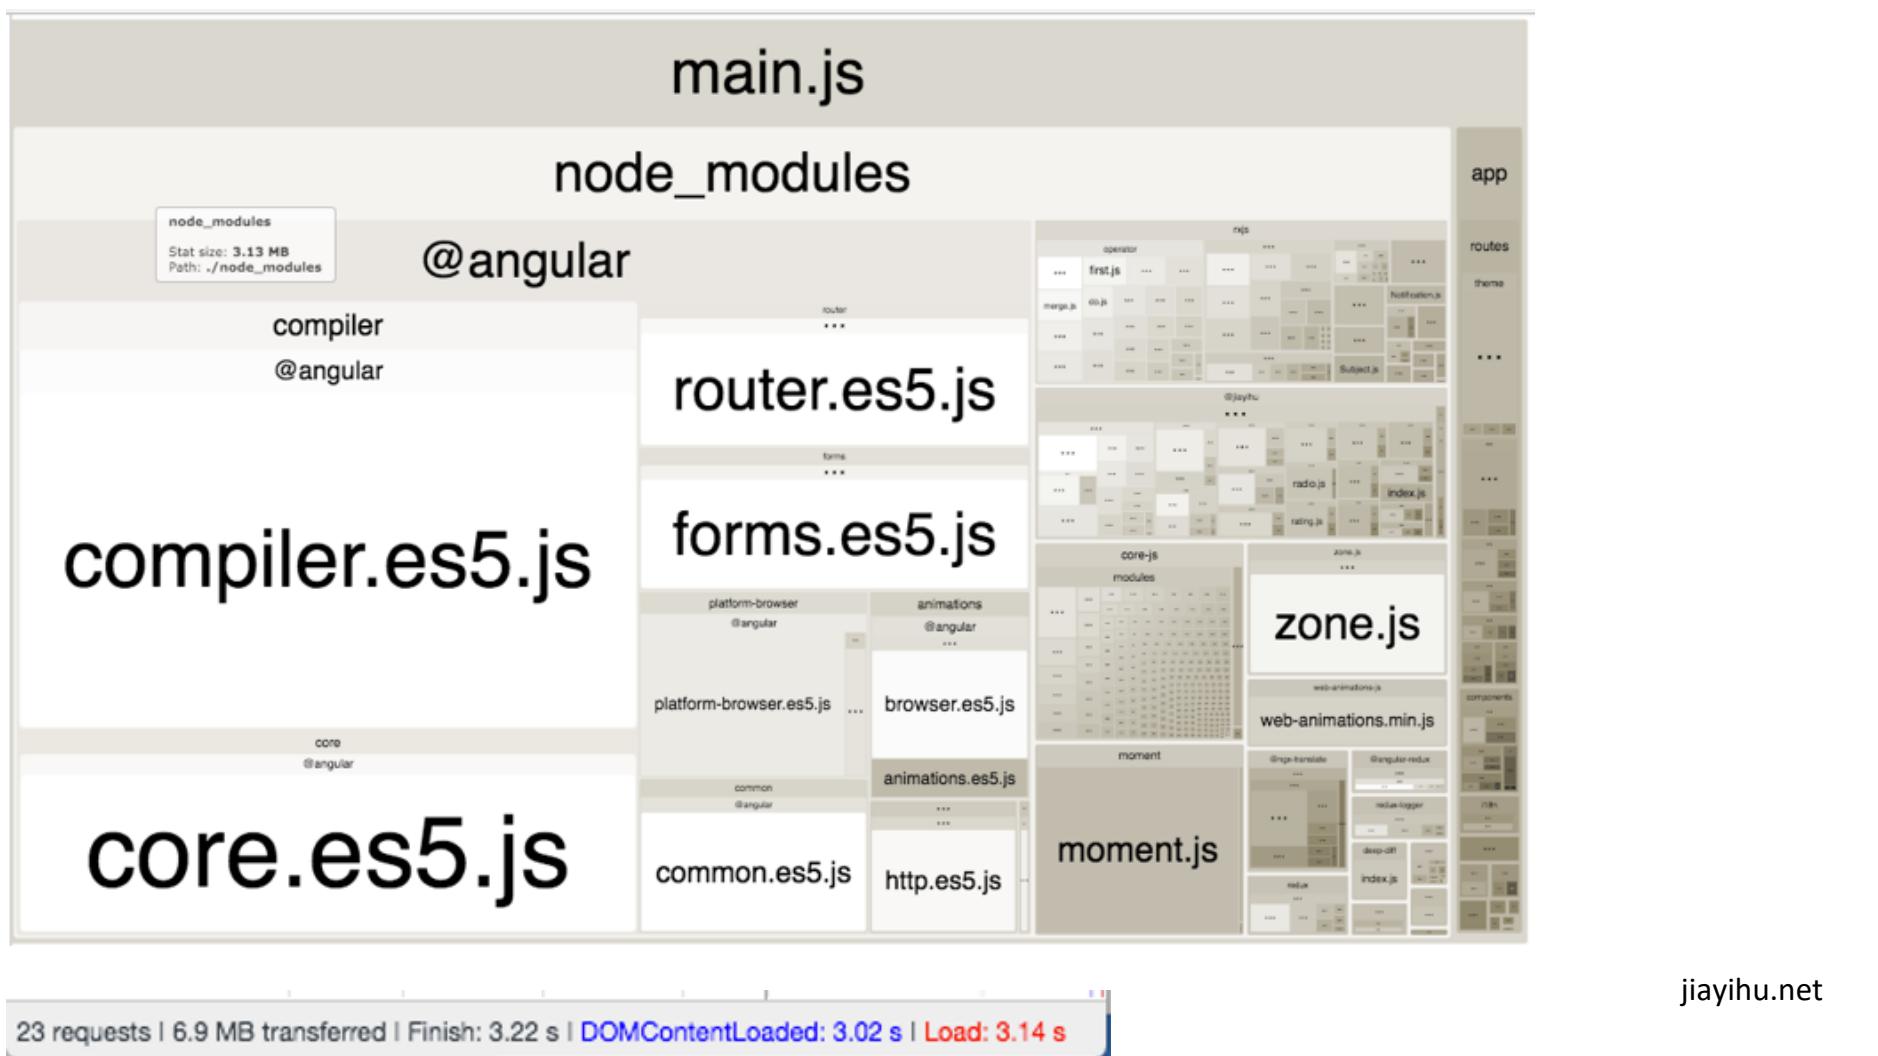

50. How Passwordless Authentication Works

51. Why Do We Need a Angular Compiler?

52. Just-in-time (JIT) compilation

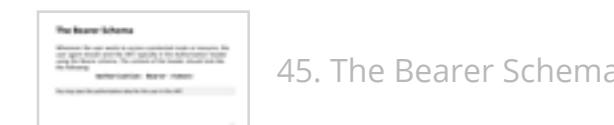

Ahead of Time compilation (AOT)

- We no longer have to ship the compiler to the client
- Since the compiled app doesn't have any HTML, and instead has the generated TypeScript code, the TypeScript compiler can analyze it to produce type errors. In other words, your templates are type safe.
- Bundlers can tree shake away everything that is not used in the application. The bundler will figure out which components are used, and the rest will be removed from the bundle.
- Since the most expensive step in the bootstrap of your application is compilation, compiling ahead of time can significantly improve the bootstrap time.

53. Source Code Shipped to Users (JiT)

54. Ahead of Time compilation (AOT)

55. Source Code Shipped to Users (AoT)

56. JiT vs AoT

AOT implications

To make AOT work the application has to have a clear separation of the **static and dynamic data** in the application. And the compiler has to be built in such a way that it **only depends on the static data**.

The information in the decorator is known statically. Angular knows the selector and the template of your component. It also knows that the component has an inputs and outputs.

Since Angular knows all the necessary information ahead of time, it can compile the application components without actually executing any application code, as a build step.

56. JIT vs AoT

57. AOT implications

Server Side Rendering

Browsers have to do a heavy work before it can display the first pixel on the screen.

Flow for **server pre-rendering**:

- Generate static HTML with build tool
- Deploy generated HTML to a CDN
- Server view served up by CDN
- Server view to client view transition

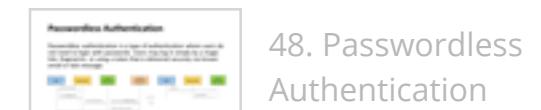

Flow for **server re-rendering**:

- HTTP GET request sent to the server
- Server generates a page that contains rendered HTML and inline JavaScript for Preboot
- Server view to client view transition

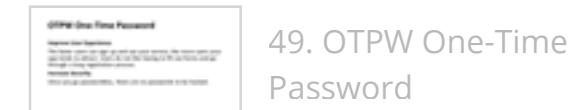

<https://universal.angular.io>

JiT vs AoT

57. AOT implications

58. Server Side Rendering

SSR: Server View to Client View Transition

Browser receives initial payload from server, user sees **Server View**.

Preboot creates hidden div that will be used for client bootstrap and starts recording events.

Browser makes async requests for additional assets.

Once external resources loaded, Angular client bootstrapping begins.

Client view is rendered to the hidden div created by **Preboot**.

Preboot events replayed in order to adjust the application state to reflect changes made by the user before Angular bootstrapped.

Preboot switches the hidden **Client View** div for the visible **Server View** div and performs some cleanup on the visible **Client View** including setting focus.

55. Source Code Shipped to Users (AoT)

56. JiT vs AoT

57. AOT implications

58. Server Side Rendering

59. SSR: Server View to Client View Transition

The Big Picture

Developer writes code in TS, run **ng build**:

- **Just-In-Time:**
Empty HTML + JS bundle with Angular code (Templates) + compiler
- **Ahead-Of-Time:**
Empty HTML + JS bundle with pure JS classes (no templates)
- **Server-Side-Rendering:**
HTML fully rendered component (server view) and fetch client view in background.

95

50. How Passwordless Authentication Works

51. Why Do We Need a Angular Compiler?

52. Just-in-time (JIT) compilation

53. Source Code Shipped to Users (JIT)

54. Ahead of Time compilation (AoT)

55. Source Code Shipped to Users (AoT)

56. JIT vs AoT

57. AOT implications

58. Server Side Rendering

59. SSR: Server View to Client View Transition

60. The Big Picture

Main Points

- The central part of Angular is its compiler.
- The compilation can be done just in time (at runtime) and ahead of time (as a build step).
- The AOT compilation creates smaller bundles, tree shakes dead code, makes your templates type-safe, and improves the bootstrap time of your application.
- The AOT compilation requires certain metadata to be known statically, so the compilation can happen without actually executing the code.

Deploy for Production

› `ng build --prod` // When you run the `ng build` command, it creates a `/dist` folder.

Adding the production flag reduce the bundle size nearly an 83% reduction:

- Removes unwanted white space by minifying files.
- Uglifies files by renaming functions and variable names.
- AoT compilation

The app will work if you're uploading it to the root public folder, such as `website.com`, but if it's within a sub folder such as `website.com/subfolder`, you can specify the `--base-href` flag during the build process based on the folder structure of where the app will be placed.

If you want to use `/app` as an application base for router and `/public` as base for your assets:

› `ng build --prod --base-href /app --deploy-url /public`

Adding CSS and JavaScript to a Project

Adding external files directly to your index.html file is not a good practice, because files won't get bundled. What we ultimately want to end up with is code that we can ship all as one unit.

If you've already done a build, you should have a folder named "**dist**" with all the files you need to run your application. What we want to end up with is ALL of the files we need for our application in that directory all bundled and minified.

When CSS and HTML files get compiled into our bundles, they all end up as JavaScript.

Alternative Way

An alternate way is to place **@import** statements in your application level CSS file (**styles.css** in an Angular CLI project). This works best if you are referencing external files (URLs) or files that you can access from your resources directory.

```
@import "~bootstrap/dist/css/bootstrap.min.css";
```

OR

```
@import url('https://unpkg.com/bootstrap@3.3.7/dist/css/bootstrap.min.css');
```
